Problems
Solutions ($\Lambda \rightarrow$)

- We start with an arbitrary collection, \mathcal{TC} , of type constants (which may include *Integer*, *Boolean*, etc.)
- The set, *Type*, of *type expressions* of the simply-typed λ -calculus, $\Lambda \rightarrow$, is given by:

$$T \in \textit{Type} ::= C \mid T_1 \rightarrow T_2 \mid (T)$$

where $C \in \mathcal{TC}$

- Clearly this definition is parameterized by \mathcal{TC} , but for simplicity, we do not show this in the notation *Type*

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

$$T \in \text{Type} ::= C \mid T_1 \rightarrow T_2 \mid (T)$$

- The set *Type* is composed of
 - [1] Type constants *C* from the set \mathcal{TC} ,
 - [2] Expressions of the form $T_1 \rightarrow T_2$ where $T_1, T_2 \in \text{Type}$
 - [3] Expressions of the form (T) where $T \in \text{Type}$
- In other words, type expressions are built up from type constants, *C*, by constructing function types, and using parentheses to group type expressions.
- Typical elements of *Type* include *Integer*, *Boolean*, $\text{Integer} \rightarrow \text{Integer}$, $\text{Boolean} \rightarrow (\text{Integer} \rightarrow \text{Integer})$, and $(\text{Boolean} \rightarrow \text{Integer}) \rightarrow \text{Integer}$

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice
Problems
Solutions ($\Lambda \rightarrow$)

- When defining the expressions of a typed programming language, we need to distinguish the **pre-expressions** from the **expressions** of the language
- The *pre-expressions* are syntactically correct, but may not be *typeable*, while the *expressions* are those that pass the *type checker*

Constant Expression

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- Expressions of the typed λ -calculus can include elements from an arbitrary set of constant expressions, \mathcal{EC}
- Each of these constants comes with an associated type
- For example, \mathcal{EC} might include constants representing integers such as 0, 1, . . . , all with type *Integer*; booleans such as true and false, with type *Boolean*; and operations such as plus and mult with type

Integer \rightarrow *Integer* \rightarrow *Integer*

(prefix versions of "+" & "*")

- We will leave \mathcal{EC} unspecified most of the time, using constant symbols freely where it enhances our examples
- As above, we will underline constants of the language to distinguish them

Pre-Expression

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice Problems
Solutions ($\Lambda \rightarrow$)

- The collection of **pre-expressions** of the typed λ -calculus, $\mathcal{TLC}\mathcal{E}$ (*Typed Lambda Calculus Expressions*), are given with respect to
 - a collection of type constants, \mathcal{TC} ,
 - a collection of expression identifiers, \mathcal{EI} , and
 - a collection of expression constants, \mathcal{EC} :

$$M, N \in \mathcal{TLC}\mathcal{E} ::= c \mid x \mid \lambda(x : T). M \mid M N \mid (M)$$

where $x \in \mathcal{EI}$ and $c \in \mathcal{EC}$

- As with types, this definition is parameterized by the choice of \mathcal{TC} , \mathcal{EI} , and \mathcal{EC}

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

$$M, N \in \mathcal{TLC\mathcal{E}} ::= c \mid x \mid \lambda(x : T). M \mid M N \mid (M)$$

- Pre-expressions of $\mathcal{TLC\mathcal{E}}$, typically written as M , N (or variants decorated with primes or subscripts), are composed of constants, c , from \mathcal{EC} ; identifiers, x , from \mathcal{EI} ; function definitions, $\lambda(x : T). M$; and function applications, $M N$
- Also, as with type expressions, any pre-expression, M , may be surrounded by parentheses, (M)
- All formal parameters in function definitions are associated with a type
- We treat function application as having higher precedence than λ -abstraction. Thus $\lambda(x : T). M N$ is equivalent to $\lambda(x : T). (M N)$

Sum Type

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice
Problems
Solutions ($\Lambda \rightarrow$)

- In order to complete the specification of expressions of the typed λ -calculus, we need to write down type-checking rules that can be used to determine if a pre-expression is type correct
- Expressions being type checked often include identifiers, typically introduced as formal parameters along with their types
- In order to type check expressions we need to know what the type is for each identifier
- The collection of expressions of the typed λ -calculus with respect to \mathcal{TC} and \mathcal{EC} is the collection of pre-expressions which can be assigned a type by the type-checking rules

Free & Bound Identifiers

Module M05

Partha Pratim Das

$\Lambda \rightarrow$

Type Expression

Pre-Expression & Expression

Type-checking Rules

Example

Practice Problems

$\Lambda_{rr} \rightarrow$

Types

Tuple Type

Record Type

Sum Type

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- **Definition:** The collection of **free identifiers** of an expression M , written $FI(M)$, is defined as follows:

$$[1] \quad FI(c) \triangleq \phi, \text{ for } c \in \mathcal{EC}$$

$$[2] \quad FI(x) \triangleq \{x\}, \text{ for } x \in \mathcal{EI}$$

$$[3] \quad FI(\lambda(x : T). M) \triangleq FI(M) - \{x\}$$

$$[4] \quad FI(M \ N) \triangleq FI(M) \cup FI(N)$$

- When an identifier is used as a formal parameter of a function, its occurrences in the function body are no longer free – we say they are **bound identifiers**
- For example

$$FI((plus \ x) \ y) = \{x, y\}$$

but

$$FI(\lambda(x : Integer). (plus \ x) \ y) = \{y\}$$

Static Type Environment, \mathcal{E}

Λ_{rr}

Types

Tuple Type

Record Type

Sum Type

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice
Problems
Solutions ($\Lambda \rightarrow$)

- Bound identifiers are supplied with a type when they are declared as formal parameters, but free identifiers are not textually associated with types in the expressions containing them
- The type-checking rules require information about the type s of free identifiers
- **Static type environment**, \mathcal{E} associates types with free expression identifiers
- **Definition:** A static type environment, \mathcal{E} , is a finite set of associations between identifiers and type expressions of the form $x : T$, where each x is unique in \mathcal{E} and T is a type
- If $x : T \in \mathcal{E}$, then we sometimes write $\mathcal{E}(x) = T$

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- **Type-checking rules** can be in one of two forms

[1] A rule of the form

$$\mathcal{E} \vdash M : T$$

OR

$$\frac{}{\mathcal{E} \vdash M : T}$$

indicates that with the typing of free identifiers in \mathcal{E} , the expression M has type T

[2] A rule of the form

$$\frac{\mathcal{E} \vdash M_1 : T_1, \dots, \mathcal{E} \vdash M_n : T_n}{\mathcal{E} \vdash M : T}$$

indicates that with the typing of free identifiers in \mathcal{E} , the expression M has type T
if the assertions above the horizontal line all hold

- The hypotheses of a rule all occur above the horizontal line, while the conclusion is placed below the line

Problems
Solutions ($\Lambda \rightarrow$)

- Read the rules from the bottom-left in a clockwise direction (example, Application Rule)

$$\frac{\mathcal{E} \vdash M : T \rightarrow T', \mathcal{E} \vdash N : T}{\mathcal{E} \vdash M N : T'}$$

- To type check $M N$ under \mathcal{E} , use Application Rule
- Proceed clockwise to the top of the rule – now we need to find the types of M and N under \mathcal{E}
- If M has type $T \rightarrow T'$ and N has type T , then the resulting type of $M N$ is T'

Problems

Solutions ($\Lambda \rightarrow$)

Function Rule:

$$\frac{\mathcal{E} \cup \{x : T\} \vdash M : T'}{\mathcal{E} \vdash \lambda(x : T).M : T \rightarrow T'}$$

- As the formal parameter of the function occurs in the body, the formal parameter and its type need to be added to the environment when type checking the body
- Thus if $\lambda(x : T). M$ is type checked in environment \mathcal{E} , then the body, M , should be type checked in the environment $\mathcal{E} \cup \{x : T\}$. (Recall that the environment $\mathcal{E} \cup \{x : T\}$ is legal only if x does not already occur in \mathcal{E})
- For example, in typing the function $\lambda(x : \text{Integer}).x + \underline{1}$, the body, $x + \underline{1}$, should be type checked in an environment in which x has type *Integer*

Type-checking Rules: Application Rule

Module M05

Partha Pratim
Das

Application Rule:

$$\frac{\mathcal{E} \vdash M : T \rightarrow T', \mathcal{E} \vdash N : T}{\mathcal{E} \vdash M N : T'}$$

A function application $M N$ has type T' as long as the type of the function, M , is of the form $T \rightarrow T'$, and the actual argument, N , has type T , matching the type of the domain of M

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice
Problems
Solutions ($\Lambda \rightarrow$)

Because the body is a function application, we type check the function and argument to make sure their types match

Type checking the argument is easy as:

$$\mathcal{E}_1 \vdash x : \text{Integer} \quad \dots (1)$$

by *Identifier Rule*

$$\mathcal{E} \cup \{x : T\} \vdash x : T$$

Type-checking Rules: Example 1

Module M05

Partha Pratim
Das

Type-checking plus x is a bit more complex, because it is a function application as well. However, by *Constant Rule*,

$$\mathcal{E}_1 \vdash \text{plus} : \text{Integer} \rightarrow \text{Integer} \rightarrow \text{Integer} \quad \dots (2)$$

and by *Identifier Rule*, we again get

$$\mathcal{E}_1 \vdash x : \text{Integer}$$

Because the domain of the type of plus and the type of x are the same,

$$\mathcal{E}_1 \vdash \text{plus } x : \text{Integer} \rightarrow \text{Integer} \quad \dots (3)$$

by lines (2), (1), and the *Application rule*

$$\frac{\mathcal{E} \vdash M : T \rightarrow T', \mathcal{E} \vdash N : T}{\mathcal{E} \vdash M N : T'}$$

Practice
Problems
Solutions (Λ^{\rightarrow})

- Ordered tuples are written in the form $\langle a_1, \dots, a_n \rangle$ and have type $T_1 \times \dots \times T_n$ where each T_i is the type of the corresponding a_i
- Tuple types represent the domain of functions taking several parameters
- The projection operations, $proj_i$, extract the i^{th} component of a tuple. Thus

$$proj_i(\langle a_1, \dots, a_n \rangle) = a_i$$

$\Lambda_{rr}^{\rightarrow}$: Tuple Type: n -ary Functions

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions (Λ^{\rightarrow})

- We write

$$\lambda(id_1 : T_1, \dots, id_n : T_n). M$$

as an abbreviation for

$$\lambda(arg : T_1 \times \dots \times T_n). [proj_i(arg)/id_i]_{i=1, \dots, n} M$$

- Thus an n -ary function is an abbreviation for a function of a single argument that takes an n -tuple
- When expanded, each of the individual parameters is replaced by an appropriate projection from the n -tuple
- For example:

$$\lambda(x : Integer, y : Integer). plus \times y$$

abbreviates

$$\lambda(p : Integer \times Integer). plus (proj_1(p)) (proj_2(p))$$

Problems

Solutions (Λ^{\rightarrow})

- Use of tuple type has always been prevalent in programming languages for n -ary functions. Naturally we can see the direct parallel between:

$$\lambda(id_1 : T_1, \dots, id_n : T_n). M$$

and

$$T \text{ func}(T_1 \text{ id}_1, T_2 \text{ id}_2, \dots, T_n \text{ id}_n);$$

except for the syntactic differences and the need for specifying a return type

- In λ calculus the return type is deduced by type checker, while in C/C++ it is deduced and checked with the given return type for possible needs of conversion

$\Lambda_{rr}^{\rightarrow}$: Tuple Type: n -ary Functions & Semantics of C / C++

Module M05

Partha Pratim
Das

- For

$\lambda(id_1 : int, id_2 : real). M$

we have the following variants in common programming languages

Language	Function Signature	Typing
Fortran	<code>integer x real y int function func(x, y)</code>	static
PASCAL	<code>function func(x: integer, y: real): integer;</code>	static
C/C++	<code>int func(int x, double y);</code>	static
Java	<code>int func(int x, double y);</code>	static
Python	<code>def func(x, y):</code>	dynamic

Problems

Solutions (Λ^{\rightarrow})

- Records are written in the form

$$\{|l_1 : T_1 := M_1, \dots, l_n : T_n := M_n|\}$$

- Notice that each labeled field is provided with its type
- The type of a record of this form is written as

$$\{|l_1 : T_1, \dots, l_n : T_n|\}$$

- Dot notation is used to extract the value of a field from a record:

$$\{|l_1 : T_1 := M_1, \dots, l_n : T_n := M_n|\}.l_i = M_i$$

$\Lambda_{rr}^{\rightarrow}$: Record Type & Semantics of C / C++

Derived Rules

Practice

Problems

Solutions (Λ^{\rightarrow})

- The record type

$$\{|l_1 : T_1, \dots, l_n : T_n|\}$$

in λ parallels struct in C and struct or class in C++. So

$$\{|re : real, im : real|\}$$

is

```
struct Complex {
    double re;
    double im
}
```

in C/C++ and

```
class Complex { public:
    double re;
    double im
}
```

in C++

Solutions (Λ^{\rightarrow})

- A sum type,

$$T_1 + \cdots + T_n$$

represents a disjoint union of the types, where each element contains information to indicate which summand it comes from, even if several of the T_i 's are identical

- If M is an expression from a type T_i , the expression

$$\text{in}_i^{T_1, \dots, T_n}(M)$$

injects the value M into the i^{th} component of the sum $T_1 + \cdots + T_n$

Problems

Solutions (Λ^{\rightarrow})

- If M is an expression of type $T_1 + \cdots + T_n$, then an expression of the form

case M of $x_1 : T_1$ then E_1 || \cdots || $x_n : T_n$ then E_n

represents a statement listing the possible expressions to evaluate depending on which summand M is a part of

- Thus if M was created by

$in_i^{T_1, \dots, T_n}(M')$

for some M' of type T_i then evaluating the *case* statement will result in evaluating E_i using M' as the value of x_i

Practice

Problems

Solutions (Λ^{\rightarrow})

- The sum type

$$S = T_1 + \cdots + T_n$$

is a collection of disjoint types which is severally important in all languages

- In C, this need has been met by

$$\text{union } \{ T_1 x_1; \cdots ; T_n x_n \}$$

wrapped in a

$$S = \text{struct } \{ \text{int tag; union } \{ \cdots \} \}$$

with a *type tag* (*tag*) – an effective but weak and error-prone solution where

$$\text{myCase} \equiv \text{case } M \text{ of } x_1 : T_1 \text{ then } E_1 \parallel \cdots \parallel x_n : T_n \text{ then } E_n$$

is a

$$\text{switch } (M.\text{tag}) \{ \text{case } x_1 : E_1; \cdots ; \text{case } x_n : E_n; \}$$

and the injection

$$\text{in}_i^{T_1, \cdots, T_n}(M')$$

is achieved by setting *M.tag* = *i* and *xi* to *M'*.

Practice

Problems

Solutions (Λ^{\rightarrow})

- In C++, this is achieved by (*smarter*) dynamic dispatch where T_1, \dots, T_n are specialized from the sum type S as the abstract base class
- With this *case M of* is implemented as a (*pure virtual*) method `myCase()` in S which is overridden by the implementation of E_i in every *class* T_i
- Injection of M' of T_i is obtained by constructing an object of T_i and setting a *const* S reference to it
- Invocation of `M.myCase()` correctly calls the corresponding computation of E_i by run-time polymorphism (*virtual function*)
- We elucidate both with examples

Solutions (Λ^{\rightarrow})

- The following function takes elements of the sum type, *Integer + Integer*, and uses *case* to compute an integer value
- The value depends on whether the element of the sum type arose by injecting an integer as the first component or the second component:

$$\begin{aligned} \text{myCase} = \lambda(z : \text{Integer} + \text{Integer}). \text{case } z \text{ of} \\ x : \text{Integer} \text{ then } x + \underline{1} \parallel \\ y : \text{Integer} \text{ then } y * \underline{2} \end{aligned}$$

- Hence,
 - *myCase* $M_1 = \underline{6}$
 - *myCase* $M_2 = \underline{14}$

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 1: Using union in C++

Int + Int: $M_1 \equiv in_1^{Int, Int}(5)$, $M_2 \equiv in_2^{Int, Int}(7)$

*myCase = $\lambda(z : Int + Int). \text{case } z \text{ of } x : Int \text{ then } x + 1 \parallel y : Int \text{ then } y * 2$*

```
#include <iostream>
enum tag_type { field1 = 0, field2 = 1 };
union union_type {
    int i1; /* field1, Int */ int i2; // field2, Int
    union_type(enum tag_type tag, int i) { (tag == field1)? i1 = i: i2 = i; }
};
struct sum_type {          // Int + Int
    enum tag_type tag; // tag to remember injection component
    union union_type u;
    sum_type(enum tag_type t, int i): tag(t), u(tag, i) { }
};
int myCase(struct sum_type u) {          // z: Int + Int
    switch (u.tag) {                    // case z of
        case field1: return u.u.i1 + 1; // x: Int then x + 1 ||
        case field2: return u.u.i2 * 2; // y: Int then y * 2
    }
}
int main() {
    struct sum_type M1 = field1, 5; // M1 = in1(5)
    struct sum_type M2 = field2, 7; // M2 = in2(7)
    std::cout << myCase(M1); // 6
    std::cout << myCase(M2); // 14
}
```

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 1: Using Dynamic Dispatch in C++

$Int + Int$: $M_1 \equiv in_1^{Int, Int}(5)$, $M_2 \equiv in_2^{Int, Int}(7)$

$myCase = \lambda(z : Int + Int). \text{case } z \text{ of } x : Int \text{ then } x + 1 \parallel y : Int \text{ then } y * 2$

```
#include <iostream>
struct sum_type {           // Int + Int
    virtual int myCase() const = 0; // myCase type switch. z: Int + Int. case z of
};
struct T1: public sum_type { // T1 = int Wrapped
    int data; T1(int d): data(d) { }
    int myCase() const {      // case of T1 type action code
        return data + 1;     // x: Int then x + 1
    }
};
struct T2: public sum_type { // T2 = int Wrapped
    int data; T2(int d): data(d) { }
    int myCase() const {      // case of T2 type action code
        return data * 2;     // y: Int then y * 2
    }
};
int main() {
    const sum_type& M1 = T1(5); // M1 = in1(5)
    const sum_type& M2 = T2(7); // M2 = in2(7)
    std::cout << M1.myCase();   // 6
    std::cout << M2.myCase();   // 14
}
```

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 2

- The expression

$$M_1 \equiv in_1^{Integer, Integer \rightarrow Integer}(\underline{47})$$

is an expression with type

$$Integer + (Integer \rightarrow Integer)$$

It represents injecting the number 47 into the sum type as the first component

- The expression

$$M_2 \equiv in_2^{Integer, Integer \rightarrow Integer}(\underline{succ})$$

is an expression with type

$$Integer + (Integer \rightarrow Integer)$$

It represents injecting the function $\underline{succ} : Integer \rightarrow Integer$ into the sum type as the second component

Practice

Problems

Solutions (Λ^{\rightarrow})

$$\text{isFirst} = \lambda(y : \text{Integer} + (\text{Integer} \rightarrow \text{Integer})). \text{case } y \text{ of}$$
$$x : \text{Integer} \text{ then } x + \underline{1} \parallel$$
$$f : \text{Integer} \rightarrow \text{Integer} \text{ then } f \ 0$$

- The parameter y comes from a sum type, the first of whose summands is Integer , while the second is the function type, $\text{Integer} \rightarrow \text{Integer}$
- If the parameter comes from the first summand, then it must represent an integer, x , and one is added to the value
- If it comes from the second summand, then it represents a function from integers to integers, denoted f , and the function is applied to 0
- Thus the value originally injected in the sum is represented by an identifier in the appropriate branch of the case, and thus can be used in determining the value to be returned.

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 2: Using union in C++

$Int + (Int \rightarrow Int): M_1 \equiv in_1^{Int, Int \rightarrow Int}(47), M_2 \equiv in_2^{Int, Int \rightarrow Int}(succ)$

    std::cout << M3.myCase(); // 17
}
```

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 4: Using Dynamic Dispatch in C++

Since $Int + (Int + Int) \equiv Int + Int + Int$, the following

$Int + (Int + Int) : M_1 \equiv in_1^{Int, Int+Int}(\underline{10})$, $M_2 \equiv in_2^{Int, Int+Int}(in_1^{Int, Int}(\underline{12}))$, $M_3 \equiv in_2^{Int, Int+Int}(in_2^{Int, Int}(\underline{14}))$
 $isFirst = \lambda(y : Int + (Int + Int)). \text{ case } y \text{ of } x : Int \text{ then } \underline{plus} \ x \ \underline{1} \ || \ s : Int + Int \text{ then}$
 $\lambda(z : Int + Int). \text{ case } z \text{ of } a : Int \text{ then } \underline{plus} \ a \ \underline{2} \ || \ b : Int \text{ then } \underline{plus} \ b \ \underline{3}$

can be simplified to:

$Int + Int + Int : M_1 \equiv in_1^{Int, Int, Int}(\underline{10})$, $M_2 \equiv in_2^{Int, Int, Int}(\underline{12})$, $M_3 \equiv in_3^{Int, Int, Int}(\underline{14})$
 $isFirst = \lambda(y : Int + Int + Int). \text{ case } y \text{ of } x : Int \text{ then } \underline{plus} \ x \ \underline{1} \ ||$
 $a : Int \text{ then } \underline{plus} \ a \ \underline{2} \ || \ b : Int \text{ then } \underline{plus} \ b \ \underline{3}$

This changes the type by construction, but gives a simpler equivalent type for injection and case. We illustrate with a flattened hierarchy below:

$\Lambda_{rr}^{\rightarrow}$: Sum Type: Example 4: Using Dynamic Dispatch in C++

$Int + Int + Int : M_1 \equiv in_1^{Int, Int, Int}(\underline{10}), M_2 \equiv in_2^{Int, Int, Int}(\underline{12}), M_3 \equiv in_3^{Int, Int, Int}(\underline{14})$
 $isFirst = \lambda(y : Int + Int + Int). \text{ case } y \text{ of } x : Int \text{ then } \underline{plus} \ x \ 1 \ ||$
 $a : Int \text{ then } \underline{plus} \ a \ 2 \ || \ b : Int \text{ then } \underline{plus} \ b \ 3$

```
#include <iostream>
struct sum_type {                                // Int + Int + Int

Problems
Solutions (Λ^{\rightarrow})

- Reference types represent updatable variables
- If M has type

$Ref\ T$

we can think of it as denoting a location which can hold a value of type T

- The expression

$val\ M$

will denote the value stored at that location

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions (Λ^{\rightarrow})

- In most procedural languages, programmers are not required to distinguish between variables (representing locations) and the values they denote
- The compiler or interpreter automatically selects the appropriate attribute (*location* or *l-value* versus *value* or *r-value*) based on context without requiring the programmer to annotate the variable

- In C, for

$x = y;$

x denotes *l-value* while y denotes *r-value*

- In ML (which supports references)
 - ▷ Write $!x$ when the *value* stored in x is required, while x alone always denotes the *location*
- In C
 - ▷ Write $\&x$ when the *location* of x is required in an *r-value* context, where x alone denotes the *value* stored in x

Types

Tuple Type

Record Type

Sum Type

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions (Λ^{\rightarrow})

- The *null* expression is a special constant representing the null reference, a reference that does not point to anything
- Evaluating the expression

val null

will always result in an error

- If *M* is a reference, with type *Ref T*, and *N* has type *T*, then the expression

M := N

denotes the assignment of *N* to *M* – the value of *N* is stored in the location denoted by *M*

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice
Problems
Solutions (Λ^{\rightarrow})

- We ignore the array type because *an array is as good as its index function* (when the memory is not considered)

- For example,

```
int a[3] = {5, 3, 8};
```

may be modeled as an index function:

```
int aIndex(int i) {  
    switch (i) {  
        case 0: return 5;  
        case 1: return 3;  
        case 2: return 8;  
    }  
}
```

Types

Tuple Type

Record Type

Sum Type

Reference Type

Array Type

Type Expression

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions (Λ^{\rightarrow})

- Of course, for making assignments to array elements, we need more tricks. In the context of `a[1] = 4;`, `aIndex()` changes from

`((0, 5), (1, 3), (2, 8))`

to

`((0, 5), (1, 4), (2, 8))`

- So every assignment needs a *higher order function* `aAssign(aIndex(), indexToItem, value)` that returns function `aIndex()`
- Also, we need to support *subtype* (*subrange of Integer*) for the index type
- We need further work (including *modeling memory*) to ensure *contiguous locations* for an array

Problems

Solutions ($\Lambda \rightarrow$)

- Let \mathcal{L} be an infinite collection of labels, and let \mathcal{TC} be a collection of type constants
- The type expressions of $\Lambda_{rr}^{\rightarrow}$ are given by the following grammar:

$$T \in \text{Type} ::= C \mid$$

$$\text{Void} \mid$$

$$T_1 \rightarrow T_2 \mid$$

$$T_1 \times \cdots \times T_n \mid$$

$$\{l_1 : T_1, l_2 : T_2, \dots, l_n : T_n\} \mid$$

$$T_1 + \cdots + T_n \mid$$

$$\text{Ref } T \mid$$

$$\text{Command}$$

where $l_i \in \mathcal{L}$, and, as before, $C \in \mathcal{TC}$ represents type constants (like *Integer*, *Double*, etc.)

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- **Void** Type
 - The type **Void** is the type of zero tuples used as the return type of commands or statements and as the parameter type for parameterless functions
 - It has only one (trivial) value, $\langle \rangle$
- Function Types
- Product (tuple) Types
- Record Types
- Sum (or disjoint union) Types
- Reference types (the types of variables)
- **Command** Type
 - Represents the type of statements, expressions like assignments that are evaluated simply for their side effects

Pre-Expression

Module M05

Partha Pratim Das

- The collection of **pre-expressions** of $\Lambda_{rr}^{\rightarrow}, \mathcal{RLCE}$ are:

$$\begin{aligned}
 M \in \mathcal{RLCE} ::= & c \mid x \mid \langle \rangle \mid \lambda(x : T). M \mid M N \mid (M) \mid \\
 & \langle M_1, \dots, M_n \rangle \mid \text{proj}_i(M) \mid \\
 & \{ l_1 : T_1 := M_1, \dots, l_n : T_n := M_n \} \mid M.l_i \mid \\
 & \text{in}_i^{T_1, \dots, T_n}(M) \mid \\
 & \text{case } M \text{ of } x_1 : T_1 \text{ then } E_1 \parallel \dots \parallel x_n : T_n \text{ then } E_n \mid \\
 & \text{ref } M \mid \text{null} \mid \text{val } M \mid \\
 & \text{if } B \text{ then } \{ M \} \text{ else } \{ N \} \mid \\
 & \text{nop} \mid N := M \mid M; N
 \end{aligned}$$

where $x \in \mathcal{EI}$, $c \in \mathcal{EC}$, and $l_i \in \mathcal{L}$

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- Statements of a typical programming language are added here as expressions of *Command* type:
 - *if B then { M } else { N }* is conditional statement
 - *nop*, a constant, represents a statement that has no effect
 - *N := M* represents an assignment statement
 - *M; N* indicates the sequencing of the two statements. Do the first statement for the side effect and then return the value of the second
- We ignore various *loop constructs* – we shall add *recursion* later for completing the expressive power – hence, loops are not needed

Pre-Expression

Type-checking Rules

Derived Rules

Practice

Problems

Solutions ($\Lambda \rightarrow$)

- We write

$$\lambda(id_1 : T_1, \dots, id_n : T_n). M$$

as an abbreviation for

$$\lambda(arg : T_1 \times \dots \times T_n). [proj_i(arg)/id_i]_{i=1, \dots, n} M$$

- Thus an n -ary function is an abbreviation for a function of a single argument that takes an n -tuple
- When expanded, each of the individual parameters is replaced by an appropriate projection from the n -tuple
- The derived typing rule for n -ary functions is:

$$\text{\textit{n-ary function}} \quad \frac{\mathcal{E} \cup \{id_1 : T_1, \dots, id_n : T_n\} \vdash M : U}{\mathcal{E} \vdash \lambda(\{id_1 : T_1, \dots, id_n : T_n\}). M : T_1 \times \dots \times T_n \rightarrow U}$$

Solutions ($\Lambda \rightarrow$)

- We write

$let\ x : T = M\ in\ N\ end$

as an abbreviation for

$(\lambda(x : T). N)\ M$

- Thus, introducing an identifier for an expression is modeled by writing a function with that identifier as the parameter, and then applying the function to the intended value for the identifier
- The derived typing rule for *let* expressions is:

$$let\ expression \quad \frac{\mathcal{E} \cup \{x:T\} \vdash N:S, \mathcal{E} \vdash \{M:T\}}{\mathcal{E} \vdash let\ x:T = M\ in\ N\ end:S}$$
